

The goal question: does an in-game property serve the real goal?

holds only if the game Γ models the goal Q

Target mismatch

The game rewards the wrong thing: Γ 's objective $\neq Q$. A pricing rule can maximize its firm's profit while Q is consumer welfare.

Right proof, wrong goal.

Never reached

Even with Γ 's target = Q , training need not reach it: the learning dynamics cycle or settle elsewhere.

Right target, never reached.
